**Abstract.** The abstract should briefly summarize the contents of the paper in 15–250 words.

**Keywords:** First keyword  $\cdot$  Second keyword  $\cdot$  Another keyword.

## 1 Introduction

**Definition 1.** For a domain  $\mathcal{D}$ , let  $\mathcal{R}^{(i)}: \mathcal{S}^{(1)} \times \mathcal{S}^{(2)} \times \cdots \times \mathcal{S}^{(i-1)} \times \mathcal{D} \to \mathcal{S}^{(i)}$  for  $i \in [n]$ , where  $\mathcal{S}^{(i)}$  is the range space of  $\mathcal{R}^{(i)}$  be a sequence of algorithms such that  $\mathcal{R}^{(i)}(z_{1:i-1}, \cdot)$  is an  $(\epsilon_i, \delta_i)$ -DP local randomizer for all values of auxiliary inputs  $z_{1:i-1} \in \mathcal{S}^{(1)} \times \mathcal{S}^{(2)} \times \cdots \mathcal{S}^{(i-1)}$ . Let  $\mathcal{A}_R: \mathcal{D} \to \mathcal{S}^{(1)} \times \mathcal{S}^{(2)} \times \cdots \times \mathcal{S}^{(n)}$  be the algorithm that given a dataset  $x_{1:n} \in \mathcal{D}^n$ , then sequentially computes  $z_i = \mathcal{R}^{(i)}(z_{1:i-1}, x_i)$  for  $i \in [n]$  and outputs  $z_{1:n}$ . We say  $\mathcal{A}_R(\mathcal{D})$  is an  $(\epsilon_i, \delta_i)$ -DP adaptive process. Similarly, if we first sample a permutation  $\pi$  uniformly at random, then sequentially computes  $z_i = \mathcal{R}^{(i)}(z_{1:i-1}, x_{\pi_i})$  for  $i \in [n]$  and outputs  $z_{1:n}$ , we say this process is shuffled  $(\epsilon_0, \delta_0)$ -DP adaptive and denote it by  $\mathcal{A}_{R,S}(\mathcal{D})$ .

**Lemma 1 (KOV15).** Let  $R^{(i)}: D \to S$  be an  $(\epsilon_i, \delta_i)$ -DP algorithm, and  $x_0, x_1 \in D$ , then there exists two discrete random variables  $\tilde{X}_0$  and  $\tilde{X}_1$ , where

$$P(\tilde{X}_0 = x) = \begin{cases} \delta_i & \text{if } x = A, \\ \frac{(1 - \delta_i)e^{\epsilon_i}}{1 + e^{\epsilon_i}} & \text{if } x = 0, \\ \frac{1 - \delta_i}{1 + e^{\epsilon_i}} & \text{if } x = 1, \\ 0 & \text{if } x = B, \end{cases}$$

<sup>\*</sup>Corresponding author

and

$$P(\tilde{X}_1 = x) = \begin{cases} 0 & \text{if } x = A, \\ \frac{1 - \delta_i}{1 + e^{\epsilon_i}} & \text{if } x = 0, \\ \frac{(1 - \delta_i)e^{\epsilon_i}}{1 + e^{\epsilon_i}} & \text{if } x = 1, \\ \delta_i & \text{if } x = B. \end{cases}$$

The  $(\epsilon_i, \delta_i)$ -differentially private mechanism

**Lemma 2.** Given an  $(\epsilon_i, \delta_i)$ -DP adaptive process, then in the i-th step, local randomizer  $\mathcal{R}^{(i)} \colon \mathcal{D} \to \mathcal{S}$  and for any n+1 inputs  $x_1^0, x_1^1, x_2, \dots, x_n \in \mathcal{D}$ , there exists distributions  $\mathcal{Q}_1^0, \mathcal{Q}_1^1, \mathcal{Q}_1, \mathcal{Q}_2, \dots, \mathcal{Q}_n$  such that

$$\mathcal{R}^{(i)}(x_1^0) = \frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}\mathcal{W}_1^0 + \frac{1-\delta_i}{1+e^{\epsilon_i}}\mathcal{W}_1^1 + \delta_i\mathcal{W}_1,$$

$$\mathcal{R}^{(i)}(x_1^1) = \frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}\mathcal{W}_1^0 + \frac{1-\delta_i}{1+e^{\epsilon_i}}\mathcal{W}_1^1 + \delta_i\mathcal{W}_1.$$

$$\forall x_i \in \{x_2, \cdots, x_n\}, \mathcal{R}(x_i) = \frac{1 - \delta_i}{1 + e^{\epsilon_i}} \mathcal{Q}_1^0 + \frac{1 - \delta_i}{1 + e^{\epsilon_i}} \mathcal{Q}_1^1 + (1 - \frac{2(1 - \delta_i)}{1 + e^{\epsilon_i}}) \mathcal{Q}^i$$

*Proof.* For inputs  $X_0 = \{x_1^0, x_2, \dots, x_n\}$  and  $X_1 = \{x_1^1, x_2, \dots, x_n\}$ ,  $\mathcal{R}^{(i)}$  satisfies the constraints of Lemma ??, so there exists an  $(\epsilon_i, \delta_i)$ -DP local randomizer  $\mathcal{R}' : \mathcal{D} \to \mathcal{Z}$  for the *i*-th output, and post-processing function  $proc(\cdots)$  such that  $proc(\mathcal{R}'^{(i)}(x)) = \mathcal{R}^{(i)}(x)$ , and

$$P(\mathcal{R}'^{(i)}(x_1^0) = z) = \begin{cases} 0 & \text{if } z = A, \\ \frac{1 - \delta_i}{1 + e^{\epsilon_i}} & \text{if } z = 0, \\ \frac{(1 - \delta_i)e^{\epsilon_i}}{1 + e^{\epsilon_i}} & \text{if } z = 1, \\ \delta_i & \text{if } z = B. \end{cases}$$

$$P(\mathcal{R}'^{(i)}(x_1^1) = z) = \begin{cases} \delta_i & \text{if } z = A, \\ \frac{1 - \delta_i}{1 + e^{\epsilon_i}} & \text{if } z = 0, \\ \frac{(1 - \delta_i)e^{\epsilon_i}}{1 + e^{\epsilon_i}} & \text{if } z = 1, \\ 0 & \text{if } z = B. \end{cases}$$

Let  $L=\{z\in\mathcal{Z}|\mathbb{P}(\mathcal{R}'(x_1^0=z))=\frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}$  and  $\mathbb{P}(\mathcal{R}'(x_1^1=z))=\frac{1-\delta_i}{1+e^{\epsilon_i}}\}$ ,  $U=\{z\in\mathcal{Z}|\mathbb{P}(\mathcal{R}'(x_1^1=z))=\frac{1-\delta_i}{1+e^{\epsilon_i}}$  and  $\mathbb{P}(\mathcal{R}'(x_1^1=z))=\frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}\}$ . Let  $M=\mathcal{Z}\{L\bigcup U\}$  and  $p=\sum_{z\in\mathcal{L}}p_z=\sum_{z\in\mathcal{U}}p_z$ . Since conditioned on the output

lying in  $\mathcal{L}$ , the distribution of  $\mathcal{R}'(x_1^0)$  and  $\mathcal{R}'(x_1^1)$  are same. Let  $\mathcal{W}_1^0 = \mathcal{R}'(x_1^0)|L = \mathcal{R}'(x_1^1)|L$ ,  $\mathcal{W}_1^1 = \mathcal{R}'(x_1^0)|U = \mathcal{R}'(x_1^1)|U$  and  $\mathcal{W}_1 = \mathcal{R}'(x_1^0)|M = \mathcal{R}'(x_1^1)|M$ . Then

$$\mathcal{R}'(x_1^0) = \frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}\mathcal{W}_1^0 + \frac{1-\delta_i}{1+e^{\epsilon_i}}\mathcal{W}_1^1 + \delta_i\mathcal{W}_1,$$

$$\mathcal{R}'(x_1^1) = \frac{(1-\delta_i)e^{\epsilon_i}}{1+e^{\epsilon_i}}\mathcal{W}_1^0 + \frac{1-\delta_i}{1+e^{\epsilon_i}}\mathcal{W}_1^1 + \delta_i\mathcal{W}_1.$$

Further, for all  $x_i \in \{x_2, \cdots, x_n\}$ ,

$$\mathcal{R}'(x_i) \ge \frac{1 - \delta_i}{1 + e^{\epsilon_i}} \mathcal{W}_1^0 + \frac{1 - \delta_i}{1 + e^{\epsilon_i}} \mathcal{W}_1^1 + (1 - \frac{2(1 - \delta_i)}{1 + e^{\epsilon_i}}) \mathcal{W}_i.$$

Letting  $\mathcal{Q}_1^0 = proc(\mathcal{W}_1^0)$ ,  $\mathcal{Q}_1^1 = proc(\mathcal{W}_1^1)$ ,  $\mathcal{Q}_1 = proc(\mathcal{W}_1)$  and for all  $i \in \{2, \dots, n\}$ ,  $\mathcal{Q}_i = proc(\mathcal{W}_i)$ .

**Theorem 1.** For a domain D, if  $\mathcal{A}_R(\mathcal{D})$  is an shuffled  $(\epsilon_i, \delta_i)$ -DP adaptive process, then there exists a post-processing function  $proc(\cdot)$ :  $(0, 1, 2) \to \mathcal{S}^{(1)} \times \mathcal{S}^{(2)} \times \cdots \times \mathcal{S}^{(n)}$ , such that

$$T(\mathcal{A}_{R,S}(X_0), \mathcal{A}_{R,S}(X_1)) = T(proc(P_0), proc(P_1)),$$

where  $(X_0, X_1, X_2) \sim P_0, X_0 = \sum_{i=1}^{n-1} Bern(\frac{1-\delta_i}{1+e_i^{\epsilon}}), X_1 = \sum_{i=1}^{n-1} Bern(\frac{1-\delta_i}{1+e_i^{\epsilon}}), X_2 = \sum_{i=1}^{n-1} Bern(1 - \frac{2(1-\delta_i)}{1+e_i^{\epsilon}}).$ 

Proof. According to Lemma ??, for arbitrary

注意到多项分布趋近于正态分布,但是趋近速率使用Berry-Esseen bound只能达到 $O(1/\sqrt{n})$ ,这相对于洗牌模型,误差会很大.因此,这边使用连续修正的方法给出O(1/n)的收敛速率.对于二项分布和正态分布的逼近速率,见[DRS22].

$$\mathbb{P}(X=k) = \int_{k-0.5}^{k+0.5} \frac{1}{\sqrt{2\pi np(1-p)}} e^{-\frac{(x-np)^2}{2np(1-p)}} dx$$

对于多项分布Multinom(n; p/2, p/2, 1-p)和对应的正态分布 $N(\mu, \Sigma)$ ,有

$$\mu = n(p/2, p/2, 1-p)$$

 $\tilde{\mathbf{\Sigma}} = n \begin{pmatrix} \frac{p}{2}(1 - \frac{p}{2}) & -\frac{p^2}{4} & -\frac{p(1-p)}{2} \\ -\frac{p^2}{4} & \frac{p}{2}(1 - \frac{p}{2}) - \frac{p(1-p)}{2} \\ -\frac{p(1-p)}{2} & -\frac{p(1-p)}{2} & p(1-p) \end{pmatrix}$ 

,

又因为根据post-processing的相关性质知,考虑前两个分量的分布即可.因此下面考虑( $X_1, X_2$ )同正态分布的全变差即可,根据公式可以得到对应的界.

$$\alpha + \beta \ge 1 - TV(P, Q) \tag{1}$$

数值结果已经表明, 多项分布以O(1/n)的速率趋近正态, 下面给出理论证明.

Lemma 3. Let  $P \sim Multinom(n; p/2, p/2, 1-p), Q \sim N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , 那么

$$||P - Q||_{TV} = O(1/n)$$

,其中 $\|P(A)-Q(A)\|_{TV}$  表示 supremum of |P(A)-Q(A)| over all measurable sets A.

Lemma 4 (参照Lemma E.2, 67-73). Let  $F_n(x)=P(\frac{X-E(X)}{\sqrt{Var(X)}}\leq x),~X\sim Bin(n,p),$  则有

$$|F_n(x) - \Phi(x)| \le \frac{C}{n},$$

for  $n \geq 2$ .

Proof.
